# 1 Introduction

These are notes I have written in preparation for the upcoming 2017 Models of Computation exam. This year the module was run by Paul Levy (P.B.Levy@cs.bham.ac.uk). This module is about problems and *computers*. We ask ourselves:

- What problems can be solved on a computer?
- What problems can be solved on a computer with finitely many states?
- What problems can be solved on a computer with only finitely many states, but also a stack of unlimited size?
- What problems can be solved on a computer with only finitely many states, but also a tape of unlimited size that it can read and write to?
- What problems can be solved *fast* on a computer?
- What does "fast" mean anyway?
- What does *computer* mean anyway?

## 2 Language Membership Problems and Regular Expressions

### 2.1 Language Membership Problems

Suppose we have a set of characters  $\Sigma$ , which we will call the *alphabet*.

### 2.2 Regex

**Regular Expressions** are a useful notation for describing languages.

## 3 Finite State Automata

## 4 Bisimulation and Minimisation

## 5 The Halting Problem

## 6 Properties of Code

## 7 Turing Machines

## 8 Church's Thesis

## 9 Complexity and P

## 10 NP

## 11 Lambda-calculus
